- 4 [Improvements](#page-7-0)
- 5 [Further work](#page-19-0)
- 6 [Conclusions](#page-22-0)

#### <span id="page-2-0"></span>Problem statement

The goal is to:

- Ensure the survival of endangered fish by achieving balance between fishing, birth, and movement rates.
- Compare the effectiveness of different geometries of exclusion zones.
- Improve on the current mathematical model by modifying the source term.
- Finding parameter values using known data.

<span id="page-3-0"></span>[Problem statement](#page-2-0) [Single species model](#page-3-0) [Effect of geometry](#page-4-0) [Improvements](#page-7-0) [Further work](#page-19-0) [Conclusions](#page-22-0)

# Single species model

Reaction-diffusion equation:

$$
\theta_t = -\nabla \cdot \underline{q} + S(\theta, \underline{x}). \tag{1}
$$

Using Fick's law we get

$$
\theta_t = \nabla . \left[ D(\theta) \nabla \theta \right] + f(\underline{x}) R(\theta). \tag{2}
$$

Possible modifications:

- Consider a time-dependent domain. Using the Reynolds transport theorem we can show that equation (1) still holds with  $q = -D(\theta)\nabla\theta + \theta u$  where *u* is the velocity of the domain.
- Previous models for circular geometries use  $f(r) = 1$  and  $R(\theta) = s\theta(1 - \theta/m)$ . We will consider a Gaussian distribution. イロト (御) (漫) (漫) (漫) 三重

## <span id="page-4-0"></span>Comparison of different geometries

We first linearise the governing equation for small *θ* and small |∇*θ*| which gives

$$
\theta_t = D(0)\nabla^2 \theta + s\theta. \tag{3}
$$

5 / 23

## Comparison of different geometries

Now consider a rectangular domain with length *a* and width *b*. For now let  $f(x, y) = 1$ . Use separation of variables to get a basis of solutions. We find that

$$
\theta = A \exp[A_{lm}t] \sin(xl\pi/a) \sin(ym\pi/b), \tag{4}
$$

where

$$
A_{lm} = -D_0 \left( \frac{m^2 \pi^2}{b^2} + \frac{l^2 \pi^2}{a^2} \right) + s. \tag{5}
$$

For  $A_{11} > 0$ , the population will increase. This gives a result in terms of the hyperbolic rms length

$$
\frac{1}{\sqrt{1/(2b^2)+1/(2a^2)}} > 2\pi \sqrt{D(0)/s}.
$$
 (6)

イロンス個人 スミンスミント ミ 6 / 23

## <span id="page-6-0"></span>Comparison of different geometries

Rearranging allows us to write this expression as a ratio of area to diagonal

$$
\frac{ab}{\sqrt{a^2 + b^2}} > \pi \sqrt{2D(0)/s}.
$$
 (7)

For a square we have

$$
a > 2\pi \sqrt{D(0)/s} \tag{8}
$$

• Reduction of 2-D model to 1-D model gives

$$
a > \pi \sqrt{D(0)/s}.
$$
 (9)

• For a circular geometry

$$
a > \lambda_1 \sqrt{D(0)/s}, \quad J_0(\lambda_1) = 0. \tag{10}
$$

## Dimensionless model

#### Employ the scaling

[Problem statement](#page-2-0) [Single species model](#page-3-0) [Effect of geometry](#page-4-0) **[Improvements](#page-7-0)** [Further work](#page-19-0) [Conclusions](#page-22-0)

## Dimensionless model

#### Employ the scaling

• Variable separable solution for the population density function  $\theta = X(x)T(t)$  furnishes the general solution in *I* 

$$
T = T(0) \exp(\lambda^2 t) \tag{11}
$$

12 / 23

イロトメ 御 トメ 重 トメ 重 トー 重

**•** Two cases

Case 1: 
$$
X(x) = A_1 \cos(\omega_1 x), \quad \hat{B} - \lambda^2 > 0
$$
 (12)

**Case 2** :  $X(x) = A_1 \cosh(\omega_1 x)$ ,  $\hat{B} - \lambda^2 < 0$  (13)

where  $\omega_1^2 = Abs[(\hat{B} - \lambda^2)].$ 

• Variable separable solution for the population density function  $\theta = X(x)T(t)$  unearths the general solution in *II* 

$$
T = T(0) \exp(\lambda^2 t) \tag{14}
$$

Two cases, but we are really interested in the case where  $\alpha > 1$ .

Case A : 
$$
X(x) = A_1 \left( \cosh(\overline{\lambda} x) - \tanh(\overline{\lambda} x_2) \sinh(\overline{\lambda} x) \right)
$$
 (15)

where

$$
-\overline{\lambda}^2 = \hat{B}[(1-\alpha) - \lambda^2]
$$
 (16)

イロトメ 御 トメ 重 トメ 重 トー 重

13 / 23

Interface conditions

The dimensionless interface conditions at  $x = x_2$  are

$$
\theta = \overline{\theta}, \quad \theta_x = D\overline{\theta_x}.\tag{17}
$$

For Case 1 and Case A this leads to

$$
\frac{\sqrt{\hat{B} - \lambda^2} \coth\left[ (\hat{x} - 1)\sqrt{\hat{B} - \hat{B}\alpha - \lambda^2} \right] \tan\left[ \sqrt{\hat{B} - \lambda^2} \right]}{D\sqrt{\hat{B} - \hat{B}\alpha - \lambda^2}} = 1.
$$
\n(18)

For  $\lambda = 0$ :

$$
\frac{\coth\left[ (\hat{x} - 1)\sqrt{\hat{B} - \hat{B}\alpha} \right] \tan\left[ \sqrt{\hat{B}} \right]}{D\sqrt{1 - \alpha}} = 1.
$$

## Condition for marginal stability

The hyper-surface in (*B*ˆ, *α*, *D*, *x*ˆ) space defined by

<span id="page-14-0"></span>
$$
\frac{\coth\left[\left(\hat{x}-1\right)\sqrt{\hat{B}(1-\alpha)}\right]\tan\left[\sqrt{\hat{B}}\right]}{D\sqrt{1-\alpha}} = 1, \quad (20)
$$

separates region of different stability.

• Can use [\(20\)](#page-14-0) to evaluate conservation strategies.

### Conservation strategy

Figure: Fraction of river that must be excluded. Sample parameters:  $D = 1$ ,  $\alpha = 5$ , and  $B = 1$

# Stability analysis for modified reactive diffusion model

Environmental heterogeneous factor is a parabolic curve. • Model

$$
\theta_t = D\theta_{xx} + (1 - \epsilon x^2) B\theta \tag{21}
$$

Variable separable solution  $\theta = e^{At}Q(x)$ , where

$$
Q(x) = e^{-\frac{1}{4}x^2} M\left(\frac{1}{2}a + \frac{1}{4}, \frac{1}{2}, \frac{1}{2}x^2\right)
$$
 (22)

and

$$
a = \frac{1}{2} \frac{A-B}{D(0)^{\frac{1}{2}}} \left( B \epsilon \right)^{-\frac{1}{2}}
$$

## Linear stability analysis

$$
\theta_t = D(0)\theta_{xx} + s\theta f(x),
$$

$$
\theta = P(t)Q(x),
$$

$$
A = \frac{P'(t)}{p} = D(0)\frac{Q''(x)}{Q} + s(1 - \epsilon x^2)
$$

$$
Q'' + \left[\frac{s - A}{D(0)} - \frac{\epsilon s x^2}{D(0)}\right]Q = 0,
$$

$$
\overline{x} = \frac{x}{\ell}, \ell = \frac{1}{\sqrt{2}}\left[\frac{D(0)}{\epsilon s}\right]^{\frac{1}{4}}.
$$

$$
Q'' - \left[a + \frac{1}{4}x^2\right]Q = 0,
$$

$$
a = \frac{1}{2}\left[\frac{D(0)}{\epsilon s}\right]^{\frac{1}{2}}\frac{A - s}{D(0)}.
$$

## <span id="page-18-0"></span>First approximation linear stability analysis

We consider the even solution

$$
Q(x) = l^{-2}e^{-\frac{1}{4}\overline{x}^{2}}M\left(\frac{1}{2}a + \frac{1}{4}, \frac{1}{2}, \frac{1}{2}\overline{x}^{2}\right),
$$

First zero approximation (Abramowitz Stegun) occurs when

$$
\overline{x}^2 = \frac{\pi^2 (1 + \frac{1}{4} - \frac{3}{4})^2}{1 - 2a - 1},
$$
  

$$
\overline{x}^2 = \frac{\pi^2}{-4a}.
$$

Stability cross-over

$$
2x_1 > \pi \left[\frac{D(0)}{s}\right]^{\frac{1}{2}},
$$

which concurs with findings above. Next correction by the New[t](#page-19-0)on-Raphson metho[d](#page-19-0) is less than  $1\%$  $1\%$  ( $f = 1$  $f = 1$  $f = 1$  $f = 1$  [a](#page-18-0)t [b](#page-6-0)dd[r](#page-6-0)[y](#page-7-0)[\).](#page-18-0)

イロト イ部 トイミト イモト 一毛

# <span id="page-19-0"></span>Finding parameter values using data

- We have 6000 data points for fish movement.
- Fit the probability density function:

$$
P = \alpha (\pi D_1 t)^{-1/2} \exp[-x^2/4D_1 t] +
$$
  

$$
(1 - \alpha)(\pi D_2 t)^{-1/2} \exp[-x^2/4D_2 t].
$$
 (23)

So we have two sub-populations, namely, home-bodies and travellers which was considered in the previous model.

# Statistical confirmation

- Data maintained on Oceanographic Research Institute's Cooperative Fish Tagging Project.
- Need to confirm model with paper by Bruce et al 2016.
- The diffusivity coefficient  $D = \frac{x_i^2}{2\pi t}$  $\frac{x_i}{2\pi t_i}$  will be furnished by random walk analysis.

## Numerical simulations

- Lie point symmetries of the non-linear equations.
- **•** Perturbation methods.
- Numerical solutions of the full non-linear equations.
- Question the applicability of Fick's law.
- Consider a moving boundary.

イロト イ部 トイミト イモト 一毛

## <span id="page-22-0"></span>**Conclusions**

- The square is the best geometry!
- A simple 1-D model provides a simple framework for assessing conservation strategies.
- Including the parabolic adjustment gives no further information at the lowest order.

*"So long and thanks for all the fish!"*
